Why is cell balancing a problem in a battery pack?

When battery packs are built with multiple cells in series, cell balancing becomes an issue. Cell balance occurs when all the individual cells in series have the same capacity, and as a result, the same voltage. This is not a concern for cells in parallel since parallel cells will balance each other with mutually applied voltage.

What is battery balancing?

Battery balancing is the process of equalizing the charge among individual cells within a battery or between batteries in a group to maintain consistent voltage levels and state of charge (SOC). This ensures that no cell is overcharged or undercharged, helping to prevent performance issues, capacity loss, and a shortened battery lifespan.

How do you maintain a battery balancer?

Temperature Monitoring: Always monitor the temperature of the battery pack during charging and discharging to prevent overheating. Voltage Checks: Regularly check the voltage of individual cells to ensure the balancer is functioning correctly. Isolation: Ensure that the balancer is properly insulated from the battery pack to prevent short circuits.

How do I connect a battery balancer?

Connection: Connect the balancer pins directly to the corresponding positive terminals of each cell in the 4S battery pack, with the BATT- pin connected to the battery's negative terminal. Monitoring: It is recommended to use a battery management system (BMS) in conjunction with the active balancer for comprehensive monitoring and protection.
